Notes:

• The Odds ratio is a statistical measure of the likelihood of an event occurring in two groups. An odds ratio of 1 in group A and group B means that the number of people in group A and group B with thyroid cancer is the same, group A/B greater than 1 means that more people in group A have the disease, and group B less than 1 means that fewer people have the disease.

• The segmentation shown in Figure B corresponds to the exposure range of 6–14-year-old children.
